## What is Deadlock?

■ Deadlock is the situation when a process cannot come back to ready state from its waiting stack

# Resource Allocation Graph

## ■ Notations:

- ▶  $P$ : a set of processes in memory.
- ▶  $R$ : a set of resources (e.g., regular file, pipe, device files).
- ▶  $P$ : directed edge indicates that  $P_i$  has requested for  $R_j$ .

## Resource Allocation Graph with Deadlock

■ A cycle must need to be exist in a deadlock graph:

- ▶  $P_1 \dashrightarrow R_1 \dashrightarrow P_2 \dashrightarrow R_3 \dashrightarrow P_3 \dashrightarrow R_2 \dashrightarrow P_1$
- ▶  $P_2 \dashrightarrow R_3 \dashrightarrow P_3 \dashrightarrow R_2 \dashrightarrow P_2$

## Resource Allocation Graph without Deadlock

■ A cycle does not ensure deadlock situation:

►  $P_1 \dashrightarrow R_1 \dashrightarrow P_3 \dashrightarrow R_2 \dashrightarrow P_1$

# Methods of Handling Deadlock

- Deadlock can be handled by **one** of **three** ways:
  - ▶ **Prevent or Avoid:** Take precautions.
  - ▶ **Detect and Recover:** Let system to enter deadlocked state and then take action.
  - ▶ **Pretend:** Pretend deadlock will never happen.

## State of System

- A cycle does not ensure deadlock situation:
  - ▶ Safe State: OS can allocate resources to each process in some order and still avoid a deadlock.
  - ▶ Unsafe State: Opposite of safe state. Not All unsafe states are deadlocks.
